

Between-BL fragmentation network of *Lepidium papilliferum*

Nodes = bottleneck lineages at geographic centroids (UTM 32611); size = BL habitat area, fill = BL identity (Set1 palette).
Edges = all 10 BL pairs; bolder edge = shorter pollinator reach (label gives shortest population-pair distance in km).

most biologically meaningful between-BL connectivity metric — the closest a single pollinator could ever bridge two BLs. All 10 BL pairs are >>500 m apart, confirming zero between-BL gene flow under the species' pollinator dispersal threshold.
