

B. Model build — how the species-wide expectation is set

STAGE 1 · predictor selection (10-fold cross-validation)

Lower CV-RMSE = better out-of-sample fit → wins Stage 2.

predictor	CV-RMSE	$\pm$ sd	R^2 in	AIC
crown	0.414	0.043	0.371	1379.6
crown+height	0.414	0.043	0.371	1381.1
area	0.422	0.043	0.347	1428.6
height	0.450	0.041	0.256	1593.5

→ Winner: crown (★)

STAGE 2 · refitted expectation model (all plants pooled)

Fitted value = expected $\log_{10}(\text{yield})$ for a plant of that size.
Residual = observed – expected.

Formula : $\log_{10}(\text{yield}) \sim \log c$
Coefficients : Intercept = +1.272, $\log c = +1.192$
 R^2 (in sample): 0.371
Residual SD : 0.416 $\log_{10}$ ($\approx \times / \div 2.6$)

Every row of Figure 17b is measured against this expectation.
